

# Intro to Electricity

James Woods

October 13, 2016

# What Make Electricity Interesting

- ▶ We somehow start with a fuel (Counting wind, geothermal and sunlight in this).
- ▶ Transport it from where we found it to a generating facility.
- ▶ Turn it into electricity losing some energy as heat.
- ▶ Run it along long wires to where people want to use it, losing yet more energy.
- ▶ From there send it out to every small location (losing more), and
- ▶ Because electricity is not *easily* stored, adjust the rate at which we generate electricity moment-by-moment to make sure there is just enough.

This is a logistical miracle.

# Basic Units

- ▶ *Watts = AmpsVolts* first thing everyone learns.
  - ▶ Pro tip on units, if it is someones name, capitalize it.
  - ▶ Volt is analogous to height.
  - ▶ Amp is analogous to a weight.
  - ▶ Watt is what it happens when that weight is dropped from that height.
  - ▶ DC is easy; AC is “complex”
- ▶ AC because it is a wave, has a few more components.
  - ▶ Real Power, measured in W, it is what does the work.
  - ▶ Reactive power, measured in volt-amps (var), “r” tells you it is reactive, is what pushes the electricity around.
  - ▶ Apparent Power, is in volt-amps too (VA) is when you add the two together in a vector sense.
  - ▶ Power Factor is the  $\text{Real(W)}/\text{Apparant(VA)}$ , the sign is interesting because assumes induction.

# What?

Caveat IANAE and I will do thing like call current amps and the like. Also, this is the simple, single phase, view with lots of simplifications. Reality is for engineers.

- ▶ The alternating part of AC is what causes the complication.
  - ▶ You can talk about instantaneous power but
  - ▶ Tend to talk about average power.
- ▶ With a resistive load, think light bulb, amps and volts are in sync
- ▶ Inductors and Capacitors throw amps and volts out of sync
  - ▶ Capacitors store energy in electric fields. Think a very bursty battery.
    - ▶ Amps peak *before* volts
  - ▶ Inductors store energy in magnetic fields. Think about an electromagnet in a motor.
    - ▶ Amps peak *after* volts

## AC Power to a Resistive Load

## AC Power to a Inductive Load

## AC Power to a Capacitive Load

Figure 1:

# Power Factor

- ▶ Measure it
  - ▶ Henrys are the unit for inductance/capacitance and engineers use that in calculations
  - ▶ There are also power factor meters
  - ▶ You can also check out the difference between amps and volt on oscilloscope.
- ▶ Low numbers mean the utility needs to generate more power than customer uses.
  - ▶ Can happen with low load, like a motor barely moving, but you still need the electromagnet
  - ▶ Common solution is to install capacitors somewhere to cancel out the inductor

# Why do we care about reactive power and power factors?

- ▶ Engineers have to design systems to accomodate not just the real, but real plus reactive, i.e., apparant power.
- ▶ Reactive power has to be generated.
- ▶ Not residential tariffs, but commercial and industrial tariffs charge for reactive power or have penalties for low power factors.

# kW vs kWh

- ▶ kW is instantaneous and called power
- ▶ kWh is the integral over time and called energy.
- ▶ 100 W light bulb uses  $100 \text{ Wh} = 1/10 \text{ kWh}$  per hour

# Lets Generate Some Electricity

- ▶ Turbine – spin something in a magnetic field to induce a current.
- ▶ Lots of ways to spin a turbine
  - ▶ Coal, grind it up, burn it, make steam, use steam to spin the turbine.
  - ▶ Nuclear, use the heat to make steam, use steam to spin a turbine.
  - ▶ Biomas, burn stuff to ...
  - ▶ Gas, burn it to spin a turbine ...
  - ▶ Fuel Oil or Diesel
  - ▶ Solar thermal, use the sun to make steam ...
  - ▶ Water, falling water hits a turbine and spins it
  - ▶ Wind, spin a turbine
  - ▶ etc.
- ▶ Or don't spin a turbine and go for photovoltaic, PV.

# Characteristics

- ▶ Nameplate, fully loaded under ideal conditions (kW)
- ▶ Ramp rate, how fast power (kW) can change kW/min
  - ▶ Not always constant, can differ by capacity factor (fraction of nameplate)
  - ▶ Not always symmetric, up different from down.
  - ▶ Used to follow the load.
- ▶ Heat rate, BTU in/ BTU out, only used for generation that uses a fuel.
  - ▶ 1 is impossible but  $1 \text{ kW} = 3412 \text{ BTU}$ .
  - ▶ Recent average from EIA, [https://www.eia.gov/electricity/annual/html/epa\\_08\\_01.html](https://www.eia.gov/electricity/annual/html/epa_08_01.html)

## Coal from the outside

Source

<http://appvoices.org/images/uploads/2012/02/Asheville-coal-plant-e1432059203783.jpg>

# Coal on the inside

- ▶ Pulverize the coal, picture something that can do 20 Tons/hr
- ▶ Blow it into combustion chamber to burn
- ▶ Steam turns turbine, etc. <https://youtu.be/IdPTuwKEfmA>
- ▶ Clean up
  - ▶ NO<sub>x</sub> with ammonia common but plenty of others
  - ▶ Recover fly ash and sell it, great for concrete.
  - ▶ SO<sub>x</sub>, Mercury and other. BTW Radiation

# Nuclear

Radiation to heat water and then ... similar to coal. Just a reaction chamber

# Local Reactor Columbia Generating Station

- ▶ [http://www.nuclear-power.net/wp-content/uploads/2014/11/inside\\_core.jpg?11abca](http://www.nuclear-power.net/wp-content/uploads/2014/11/inside_core.jpg?11abca)
- ▶ 1,170 MW usually runs as load following. It reacts fast enough.
  - ▶ France is ~70% nuclear and they load follow.
- ▶ Most nuclear is run as base load, i.e., all the time since low variable cost and high fixed cost.
- ▶ Palo Verde (AZ) is larger 3.3GW

## So, about nuclear

- ▶ So what to do with spent fuel.
- ▶ They probably produce less radiation than coal
- ▶ Can produce cheap power. More on this later.

# Natural Gas Conventional and Combined Cycle

# Biomass

Biomass One in Eugene. 30 MW and keeps catching on fire.

Figure 2:

# Geothermal

## Neal Hot Spring in Malheur. 30 MW

Figure 3:

# Diesel and other Fuel Oils

# Solar Thermal

# Hydro

# Wind

# Levelized Cost of Electricity (LCOE)
